Closest conjunct agreement in Spanish DPs. Syntax and beyond.¹

Violeta Demonte (CCHS-CSIC) & Isabel Pérez Jiménez (UAH)

Abstract:

This paper analyses a phenomenon not frequently dealt with in the grammar of Romance languages: closest conjunct (number) agreement [CCA] between determiners, adjectives and nouns in Spanish structures containing conjoined singular Ns: \[[\text{DP} \ D \ (A) \ [N_1 \ y \ N_2] \ (A)]\]. Using new corpus data, we apply statistical tests to assess the theoretical and empirical claims of the analysis. We first offer a description of the plural semantics of these structures. Regarding syntax, we show that, despite the plural semantics of the DP, determiners and prenominal adjectives agree with the closest conjunct (N₁) (e.g., \(\text{Una.F.SG fuerte.SG y viento.M.SG azotaron.PL la ciudad}\) ‘A heavy rain and wind battered the city’). As for postnominal adjectives, CCA with N₂ alternates with full (plural) agreement (e.g., \(\text{Una.F.SG lluvia.F.SG y viento.M.SG \{inoportuno.M.SG / inoportuno.sM.PL\} azotaron.PL la ciudad}\) ‘An inopportune rain and wind battered the city’). Within a generative framework, we analyse CCA in the prenominal field and full agreement of postnominal adjectives as syntactically derived from the interaction of the

¹ We would like to deeply thank Cedric Boeckx, Gorka Elordieta, Héctor Fernández-Alcalde, Olga Fernández-Soriano, Ángel Gallego, Irene Gil, Edita Gutiérrez, Luisa Martí, Louise McNally, Norberto Moreno, Isabel Oltra-Massuet, María-Luisa Rivero, Andrés Saab and two anonymous referees for helpful comments, suggestions and discussion of the issues addressed herein. We particularly thank Roberto Mayoral for his help with statistics. We also thank Jorge Rico and the ILLA-CSIC Phonetics Lab for invaluable assistance in developing the experimental study briefly described in section 5.2. Preliminary versions of certain sections of this paper have been presented at VII Workshop on Formal Linguistics (Curitiba 2008), Sylex 2 (Zaragoza 2010), LSRL 2010 (Seattle), CGG 2011 (Sevilla), ALFAL 2011 and Parallel Domains conference (LA 2011). We thank the audiences at these conferences for interesting questions and suggestions.

Research underlying this work has been partly supported by grants EDU 2008-01268/EDUC and FFI2009-07114 of the Spanish Ministry of Science and Innovation.
Agree operation and a reformulated theory of phi-features. CCA of postnominal adjectives is analysed to be the result of post-syntactic relations (i.e., linear adjacency).

**Keywords:** closest conjunct agreement, partial agreement, adjectival agreement, coordination, phi-feature, Agree, number

1. Introduction

_Closest conjunct agreement_ (hereafter CCA), sometimes called _partial agreement_, occurs in DPs with a conjunction of Ns when an agreeing element (a determiner or adjective)—the _target_—agrees in number and gender with the closest member of the coordination—the _controller_. (1) illustrates the phenomenon in English and (2) in Spanish; in this case the determiner agrees with the first noun of the coordination (first conjunct agreement).

(1) **This boy and girl** are eating a pizza. [King and Dalrymple 2004: 70, (3)]
In principle we take as marital children those whose mother and father are married to each other.

CCA holds irrespectively of the plural reference of the coordination of nouns, which is shown, among other tests, by syntactic plural verbal agreement when the DP is a subject. In (1) and (2) the conjunction of Ns denotes a plurality or set of individuals, i.e., these conjunctions have a split reading (we will come back to this notion in § 2.3). These conjunctions must be distinguished from the syntactically similar ones which receive a joint reading, as in example (3), where the conjoined Ns refer to a single individual, as indicated by the obligatory singular agreement triggered on the verb:

\[(3)\quad \text{El insigne historiador y arqueólogo publicó…}^{[2]}\]

\[
\text{the distinguished historian and archaeologist publish.3SG}
\]

‘The distinguished historian and archaeologist published…’

In this paper we examine structures of the type in (2) in which CCA is held between determiners and nouns in Spanish DPs. In addition to cases like (2), we consider sentences like (4) for CCA of prenominal and postnominal adjectives. Prenominal adjectives, like *inoportuna* in (4a), show a pattern of agreement identical to determiners; the contrast between (4a) and (4a’) indicates that the output of CCA can be singular or plural depending on the number of the first N. For postnominal adjectives, (4a) shows

\[
(2)\quad \text{En principio se entienden por hijos matrimoniales aquellos cuya madre y padre están casados entre si.\textsuperscript{[1]} }^3
\]

‘In principle we examine structures of the type in (2) in which CCA is held between determiners and nouns in Spanish DPs. In addition to cases like (2), we consider sentences like (4) for CCA of prenominal and postnominal adjectives. Prenominal adjectives, like *inoportuna* in (4a), show a pattern of agreement identical to determiners; the contrast between (4a) and (4a’) indicates that the output of CCA can be singular or plural depending on the number of the first N. For postnominal adjectives, (4a) shows

agreement between A (pertinaz) and the second noun of the conjunction. Yet, as shown by (4b), CCA (last or right conjunct agreement) alternates with full plural agreement: 4

(4) a. ... una inoportuna llovizna y viento pertinaz.

nos mantuvieron atados dos días en tierra firme. [3]

the.F.SG anorexia.F.SG and bulimia.F.SG nervous.F.PL cause.PRS.3PL

‘Anorexia nervosa and bulimia nervosa, (…), cause…’

This complex set of data poses interesting empirical and theoretical questions that we will be dealing with in this paper within a formal generative framework. One of our

4 Adjectives in Spanish fall into two classes regarding gender agreement: (i) those that inflect for feminine and masculine –alto ‘tall.M’ vs. alta ‘tall.F’– and (ii) those which are invariable with respect to gender marking –interesante.M/F ‘interesting’, actual.M/F ‘current’– (in the glosses, gender has not been indicated for these adjectives). In the cases under study, when full plural agreement is obtained, gender is determined by resolution: feminine when all conjuncts are feminine, masculine otherwise (see section 4.2.1).
goals is to establish the empirical domain of the phenomenon of CCA inside DPs in Spanish. Asserting the existence of this phenomenon in Romance—it has been claimed to be characteristic of Germanic languages and not to exist in Romance due to parametric reasons (Bouchard 2002, Heycock & Zamparelli 2005, Dobrovie-Sorin 2009)—could help us to take a position as to the properties of the Romance determiners and determiner phrases, though this is a task that we will certainly not undertake in this paper. Theoretically, a first question posed by this set of data is whether surface coordination of bare Ns is in fact deep coordination of Ns or NPs or if it is instead the result of an ellipsis process over two DP conjuncts (Camacho 2003). We will suggest that a non-ellipsis-based account can be developed for the paradigm presented above. Our proposal will be based on the existence of two types of phi-features and certain post-syntactic operations, which have been independently motivated in the literature to explain a larger set of data, such as agreement mismatches triggered by collective nouns or mixed Subject-Verb agreement cases.

Our analysis raises many questions as to the exact abstract representation of the DP with coordination of singular Ns. Within a generative framework, we will justify an analysis of coordination as an asymmetric structure (Munn 1993, 1999, Kayne 1994, Johannessen 1996, 1998, Progovac 1998, Camacho 2003 for Spanish and others). Regarding the internal position of pre- and postnominal adjectives in DPs, some of the questions that arise are the following: Are they all derived in the same way, for instance as specifiers of higher functional projections, their linear order being the result of leftward movement of either N or NP (Cinque 1994, 2010)? Are they (right-left) adjoined to NP (Laenzlinger 2004, Schoorlemmer 2009)? Alternatively: Are postnominal adjectives generated higher up in a reduced relative clause (Cinque 2010)?
The facts of CCA in Spanish DPs argue in favour of a non-uniform derivation for pre and postnominal adjectives. Last but not least, an important question on which this phenomenon has a bearing is the content and nature of the agreement mechanism and the level at which it applies. In generative Minimalist approaches to agreement, an \textit{Agree} operation is defined which matches/values features of \textit{Probes} and \textit{Goals} under a c-command relation (Chomsky 2001, 2004, Bhatt 2005). This abstract syntactic view combines with the assumption that later processes (such as morphological operations—van Koppen 2005—or post-syntactic linearization processes—Benmamoun, Bhatia & Polinsky 2010) may condition the final spell-out of Agree. Theoretical as well as empirical reasons will lead us to the conclusion that in CCA, syntactic and post-syntactic mechanisms interact. Importantly, in order to correctly account for the CCA facts we will also claim that Agree is a syntactic mechanism involving two types of phi-features: \textit{Index features} and \textit{Concord features}. Ns and Ds carry these two sets of features which, we claim, behave syntactically as \textit{bundles}.

The paper is organised as follows. In section 2, we undertake two tasks. First, we present the corpus analysis on which our descriptive generalizations are based. Second, we describe and clarify the basic paradigm showing that CCA (i.e., singular agreement) is obligatory for D and A in $[D \ (A) \ [N_1 \ SG \ y \ N_2 \ SG \ ]]$ structures, and optional for A, i.e., alternating with \textit{full} (plural) agreement, in $[D \ [N_1 \ SG \ y \ N_2 \ SG \ ] \ A]$ structures, in other words in DPs with postnominal adjectives. New Romance data not previously studied in the literature will be introduced. In this same section we try to briefly and schematically test the plural semantics of \textit{split reading} structures. We survey the various contexts that imply semantic plurality but still trigger singular agreement. In section 3 we deal with the underlying structure of surface coordination of singular Ns. First, we assume that
coordinate constituents are structured in a CoP, following Munn (1999), van Koppen (2005), van Koppen & Cremers (2008) and others. Second, we present the various reasons why we prefer a non-ellipsis analysis for this type of structure. In section 4 we show that CCA of D and prenominal A with the first N within the DP can be explained in terms of Agree. In this section we also provide an explanation for the fact that the whole DP has plural reference despite the singular number agreement of D and make a distinction between index and concord phi-features, following previous proposals on feature theory, both within the minimalist tradition (D’Alessandro 2004a, 2004b, Costa & Pereira 2005, López 2007, Danon 2011), and within HPSG and LFG models (Pollard & Sag 1994, Kathol 1999, Wechsler & Zlatić 2000, 2003, King & Dalrymple 2004, Villavicencio, Sadler & Arnold 2005) (also in semantic works like Sauerland 2008). In section 5 we note that full plural agreement of postnominal adjectives is also a case of syntactic Agree if postnominal adjectives are merged as predicates of a reduced relative clause (Cinque 2010: § 3.1, § 4.2, § 6.1). We provisionally explain CCA of the adjective with N₂ (that is, singular agreement) in terms of linear adjacency after spell-out.

2. Source of the data and basic paradigm

2.1. Corpus analysis

In this section we present the corpus analysis on which the empirical generalisations which sustain the theoretical proposals developed in the following sections of this paper are based. The goal of this analysis is to determine the exact agreement patterns which
determiners and adjectives give rise to in the structures in (5) (where the DP has a plural interpretation):

\[(5) \quad a. \ [\text{DP} \ D \ A \ [N_{1 \ SG} \ y \ N_{2 \ SG} ]] \\
b. \ [\text{DP} \ D \ [N_{1 \ SG} \ y \ N_{2 \ SG}] A] \]

2.1.1. Methodology

The sample of Spanish sentences used in the present corpus analysis was extracted from the online *Corpus de Referencia del Español Actual* (CREA). In order to obtain a representative sample, 7985 sentences containing the structures in (5) were randomly selected. Sentences containing superficially similar sequences (i.e., D-A-N-y-N or D-N-y-N-A sequences), but with properties different from those analysed in this paper, were not included in the sample. In particular, examples such as those in (3), where the DP refers to a single entity, were systematically excluded. Only sentences where the coordination of singular nouns can in principle receive a plural interpretation or split reading were considered (thus sentences where the DP is a subject triggering plural agreement on the verb were included; sentences where the DP is a DO, complement of a preposition, etc., that can receive a plural interpretation, were also included). In the same way, we excluded from the sample sentences where it is clear that a singular prenominal or postnominal adjective does not modify or have scope over the two conjoined nouns.

For each sentence included in the sample, we annotated 1) adjective number: *singular* or *plural*, 2) adjective position: *prenominal*, *postnominal*, 3) determiner
number (*singular or plural*)\(^5\) and 4) for the whole DP, whether this constituent was the subject of the sentence (triggering plural agreement on the verb) or not (*subject vs. non subject*). We obtained 330 tokens in which the DP is a subject, and 7655 tokens in which the DP is a non-subject that can in principle receive a split reading.

2.1.2. Results

In order to determine whether, in the structures under study, adjective number agreement (i.e., singular agreement—CCA—vs. plural or full number agreement) is linked to its prenominal or postnominal position in a significant way, *adjective number* and *adjective position* were regarded as the dependent and independent variables, respectively, in the statistical analysis. The tables in this section show the results of the cross-tabulations and Chi-Square tests for those variables. Non specific tables are offered for determiner agreement. We analyse the results concerning determiners in the text, together with the results obtained for adjectives. First, we analyse the entire sample. Secondly, we analyse the subset of the sample where the relevant DPs are subjects that trigger plural number agreement on the verb.

The results of the analysis of the relationship between adjective number agreement and adjectival position in the entire sample are shown in Table 1.

---

\(^5\) In the structures studied, the gender and number features of determines and adjectives behave as bundles with respect to agreement. See Marušič, Nevins & Saksida (2007, 2011) for the proposal that gender and number behave as *split-probes* in Participle-Subject agreement cases in Slovenian. For a recent discussion and analysis of the behaviour of number and gender features in sentence processing in Spanish see Acuña-Fariña (2009).
Table 1 shows that, in the structure in (5a), adjectives in prenominal position appear in singular in 98.5% of the cases. Prenominal plural adjectives represent only 1.5% of the total. These data show an almost categorical preference for prenominal singular adjectives in the structures under study. Only 54 examples with plural agreement were found. In these examples, the conjoined nouns are brand / type names and proper names (we will deal with these apparent exceptions in section 2.2.1). In the structure in (5b), however, postnominal adjectives show a high degree of variation with respect to number agreement (we will come back to postnominal adjectives in section 5). The differences observed between prenominal and postnominal adjectives with respect to their singular or plural agreement are statistically significant (p < .05). With respect to determiners, in the structure in (5a), the determiner invariably shows up with the same number (and gender) feature as the following adjective. In the structure in (5b), for all the 4328 examples with postnominal adjectives, the determiner agrees with N₁, that is, it bears singular agreement.

Second, we restricted the analysis of the link between adjective number agreement and adjective position to those cases where the relevant DP is a subject that
triggers plural verbal agreement. In these cases, the plural marking on the verb clearly indicates that the DP has a plural interpretation. The results are shown in Table 2.

*Table 2* Subject DPs that trigger plural verbal agreement: Adjective number by adjective position

As seen in Table 2, adjectives in prenominal position show singular agreement in 93.8% of the cases. Prenominal plural adjectives represent only 6.2% of the total. What these data show is an almost categorical preference for agreement with N₁ in the case of prenominal adjectives. The only six examples with plural adjectives also contain brand names or proper nouns (see sub-section 2.2.1). Postnominal adjectives show variation in number agreement (see section 5). The Chi-Square test shows that there exists a significant relationship between adjective number agreement and adjective position (p < .05). As for determiners, in the structure [D A [N y N]], the determiner shows up with the same features as the adjective. In the structure [D [N y N] A], the determiner always exhibits CCA with N₁.
2.1.3. Discussion

The first important observation, which sustains the analysis to be developed in this paper, is that CCA—that is, singular agreement—between D, prenominal adjectives and N₁ appears to be categorical in the structures described in (5). The examples where D and A show plural agreement are cases where the conjoined nouns are brand, type or proper names. As stated in section 2.2.1, these kinds of examples can receive an alternative analysis. With respect to postnominal adjectives, the statistical analysis shows that there exists variation in number agreement. If we consider the results in Table 2, where the DP is a subject triggering plural verbal agreement, postnominal adjectives show plural number agreement in 57.1% of the cases and singular agreement in 42.9% of the cases. As we will see in section 5, semantic factors (related to noun class or adjective class) do not determine the choice of agreement in those cases.

2.2. The basic paradigm

In this section we present the basic paradigm that emerges from the corpus analysis carried out in the previous section. With respect to the prenominal field, we would like to take as a point of departure the paradigm in (6) and (7).

(6) [{El/*Los} abdomen y pecho] aparecen relativamente
    abultados.^[6]
    swollen
‘The abdomen and chest look relatively swollen.’

(7) a. [La (fascinante) / *Las (fascinantes)] flora y
    the.F.SG fascinating.SG / the.F.PL fascinating.PL flora.F.SG and
    relieve] que lo componen.
    rugged-landscape.M.SG that it constitute.PRS.3PL
    ‘The fascinating flora and rugged landscape that constitute it.’

b. [Su (verdadero)/*Sus (verdaderos)] desarrollo y expansión
    han venido ocurriendo a partir de la segunda mitad del presente
    have.PRS.3PL been taking.place from the second half of the current
    siglo.[7]
    century
    ‘Its true development and expansion have been taking place from the second half
    of the current century onwards.’

c. [Su (admirable) / *Sus (admirables)] empuje y creatividad
    his.SG admirable.SG / his.PL admirable.PL drive.M.SG and creativity.F.SG
    lo han llevado a conseguir...
    him have.PRS.3PL taken to obtain
    ‘His admirable drive and creativity (…) lead him to obtain….’[8]

(6) and (7) are examples of CCA; in these cases D and A agree in the singular and share
the gender feature with the first N of a coordinated phrase. Plural determiners and plural
prenominal adjectives are ungrammatical. In (7a), for instance, the first conjunct is
feminine and the second is masculine while the determiner is feminine and singular; in
(7b) and (7c) the determiner agrees in singular number with N₁. Moreover, the ungrammaticality of plural determiners (*los, las, sus* in the examples in (6) and (7)) shows that CCA is obligatory for Ds.⁶ Prenominal adjectives in (7) also obey CCA. In all the examples in (7) the adjective agrees in number and gender with the first noun of the coordination. CCA of D and prenominal A with N₁ also takes place when N₁ and N₂ have different number, as can be seen in (8) (remember also example (4a')):

(8) a. [*Sus pómulos y nariz* aparecian afilados.⁹]

his.PL cheeks.M.PL and nose.F.SG seem.PST.3PL sharp

‘His cheeks and nose looked sharp.’

b. *Los ataques de [la aviación y helicópteros rusos]*

the attacks of the.F.SG aeroplanes.F.SG and helicopters.M.PL Russian.M.PL

fueron constantes.¹⁰

be.PST.3PL constant.PL

‘The attacks of the Russian aeroplanes and helicopters were constant.’

This paradigm in (6) and (7) should be completed with the sentences in (9) and (10) with postnominal adjectives.

(9) a. [*El trigo y sorgo disponible* no presentaron variantes...¹¹]

the.M.SG wheat.M.SG and sorghum.M.SG available.SG not show.PST.3PL changes

‘The wheat and sorghum available did not show any change (in their levels).’

---

⁶ CCA is obligatory for any kind of determiner, even for demonstratives, as witness the contrast between *Esta.F.SG morfología.F.SG y estructura.F.SG urbana.F.SG reflejan.PL una organización...*¹⁰ (‘This urban morphology and structure reflect an organization...’) and the ungrammatical *Éstas.F.PL morfología.F.SG y estructura.F.SG urbana.F.SG...*
b. [La agricultura y ganadería europeas]

the.F.SG farming.F.SG and cattle.F.SG European.F.PL

se han ido industrializando.\(^1\)

SE have.PRS.3PL become industrializing

‘The European farming and cattle sectors have become progressively industrialised.’

(10) [La radio y televisión pública catalanas]

the.F.SG radio.F.SG and television.F.SG public.F.SG Catalan.F.PL

negocian hoy.\(^2\)

negotiate.PRS.3PL today

‘The Catalan public radio and television corporations are negotiating today.’

Alternation between (singular) agreement of the adjective with the closest conjunct (N\(_2\)), (9a), and full (plural) agreement, (9b), shows up in this configuration.\(^7\) Note that the subject DP triggers plural agreement on the verb both in (9a) and (9b). The similar example in (10) is particularly interesting because here we find the first postnominal adjective agreeing in singular with N\(_2\), while the second takes syntactic plural agreement; the verbal predicate shows also plural agreement. (10) indicates that conjoined Ns found in these structures are available for plural agreement both within the DP and with the verbal predicate. We will come back to cases with two postnominal adjectives in section 5.2, where we explain (singular) agreement of postnominal adjectives with N\(_2\) in terms of linear adjacency.

\(^7\) Cinque (2010: § 7.3) also notes that in Italian and French (following Noailly 1999), adjectives preceding a series of singular coordinated nouns must agree in (singular) number (also in gender) with the first noun of the conjunction. Postnominal adjectives, by contrast, can show plural agreement.
In all the previous examples with pre- and postnominal adjectives the denotation of the whole DP is plural (i.e., the coordination has a group reading) and the adjective is interpreted by native speakers as a modifier of the two singular nouns. The example in (11) indicates that the postnominal adjective has in our structures scope over both conjuncts.

(11) [La destrucción y creación simultáneas] de la cultura del Nuevo Mundo.\[14\]

‘The simultaneous destruction and creation of the culture of the New World.’

This example has a reading whereby the destruction and creation of the culture take place at the same time. Collective or symmetric adjectives like simultáneo, coincidente similar, parecido, etc. (or, alternatively, a collective operator licensing the collective reading of the predicate) must scope over a plural argument. Since in this example each conjunct is singular, the collective predicate (or collective operator) must scope above the coordination phrase. The same reading would be obtained if the adjective were singular: simultánea. F.SG. Parallel examples can be found for prenominal adjectives, which show that prenominal As also modify or scope over both NP conjuncts in our structures: La simultánea destrucción y creación de la cultura del nuevo mundo ‘The simultaneous destruction and creation of the culture of the New World’.
Finally, regarding the cross linguistic nature of the paradigm, it has been claimed (Bouchard 2002, Heycock & Zamparelli 2005, Dobrovie-Sorin 2009 and others) that sentences like *This boy and girl are eating a pizza* (example (1) above) do not exist in Romance due to semantic or syntactic parametrised properties of the category Number. In fact, sentences like (12) and (13) are ungrammatical in Italian and French.

(12) *Un uomo e bambino mangiano.* [Heycock & Zamparelli 2005: (21a)]

‘A man and child are eating.’

(13) *Ce soldat et marin étaient d’accord.* [Heycock & Zamparelli 2005: (22b)]

\[this.M.SG \text{ soldier.M.SG and sailor.M.SG be.PST.3L in.agreement}\]

‘This soldier and sailor were in agreement.’

However, such sentences are frequently attested in Spanish, as can be inferred from our corpus analysis. Observe in (14) that this kind of structures with CCA also occurs in Brazilian Portuguese (see also Munn 1999 for more examples).

(14) *O presidente e amigo comeram juntos.*

‘The president and (his) friend ate together.’ [Villavicencio et al. 2005: (28)]

---

8 See King & Dalrymple (2004: § 4) for a discussion of this analysis.

9 We would like to note in passing that the kind of coordination described is very productive with pairs of semantically related nouns. In this respect, Spanish seems to be similar to Dutch (Heycock & Zamparelli 2005: 206). Most but not all conjunctions of this type are typologically classifiable as instances of a natural coordination relation: “a semantic relation in which two entities are closely related in meaning and form a conceptual unit” (Dalrymple & Nikolaeva 2006: 830). However, these are not frozen or lexicalised constructions but very productive ones, often used in both written and oral language.
To summarise, the empirical generalisation which follows from the paradigm presented thus far is as follows:

(15)  
a. CCA (with N₁) is categorical in Spanish for determiners and adjectives in the structure [D A [N₁SG y N₂SG]]

b. In the structure [D [N₁SG y N₂SG] A] CCA (with N₁) is also categorical for D but the postnominal A may take singular (showing CCA with N₂) or plural form.

2.2.1. Some apparent counterexamples

Sentences like the ones in (16), where determiners and prenominal adjectives agree in plural with the coordination, appear to be counterexamples to the empirical generalisation in (15):

(16)  
a. ...los modelos que (...) reemplazarán a los actuales Corsa y Tigra...¹⁵⁾

the models that replace.FUT.3PL to the.M.PL current.PL Corsa and Tigra

‘...The models that will replace the current Corsa and Tigra.’

b. ...a no ser que cerca anden los temibles Capirucho y Capirote...¹⁶⁾

unless near walk.PRS.SBJU.3PL the.M.PL fearsome.PL Capirucho and Capirote

‘...unless the fearsome Capirucho and Capirote are around.’
Yet there are various reasons to take the preceding examples with a grain of salt and not consider them problematic for our proposal. First, plural agreement of D-A before the conjunction N-y-N is infrequent. In our corpus we found 54 examples of this, against 3603 showing CCA. More importantly, these kinds of cases mostly fall in two patterns. On the one hand, we have examples like (16a) above with DPs in which the presence of a plural null N can be easily postulated because the surfacing name is a brand or type name (in 16a we find names of car models). In these cases the adjective can be missing (17a). Note that the null N (model) can be explicit, as in (17b):

(17) a. los Corsa y Astra \(^{[17]}\)

   the.M.PL Corsa and Astra

b. los modelos Corsa y Astra \(^{[18]}\)

   the.M.PL models.M.PL Corsa and Astra

On the other hand, we have examples with proper names that are either explicit, as in (16c)—where the names of people are found—or implicit, as in los actuales Presidente y Vicepresidente de EE.UU \(^{[19]}\) `the.M.PL current.M.PL president.M.SG and vicepresident.M.SG of the USA`, in the sense that these terms refer to unique entities. A crucial observation is that these cases require the co-occurrence of D and A, while they are ungrammatical if the adjective is absent. There are various putative hypotheses as to why proper names and names which refer to unique entities require plural agreement on the preceding determiners and modifiers. One possibility is that proper names have a different status within DPs since, first, when appearing alone they move to D to acquire referential status (Longobardi 1994), and, second, when they take a determiner this
element requires the presence of an adjective to be properly licensed (*los Capirucho y Capirote ‘the Capirucho and Capirote’ vs. los temibles Capirucho y Capirote ‘the fearsome Capirucho and Capirote’), which suggests that they behave as appositions to a specific common noun. We leave this question open for further research.

2.3. The plural semantics of DP internal N-y-N coordination

Semantically, sentences like English (1) and all the Spanish cases we have seen so far are examples of split-reading and/or group-forming and in \([\text{DP D}_\text{SG} \text{ [NSG and/y NSG]}]\) structures. In other words, they are cases where a conjunction denoting a plurality or set of individuals takes a singular determiner and/or modifier. In this subsection, we will provide a brief account of the semantics of such conjunctions (remember that these structures must be differentiated from the syntactically similar ones which receive a joint reading, such as the one in (3) above).

Heycock & Zamparelli (2005: 206) claim that these kinds of coordinations with a plural or split reading refer to pairs of individuals or denote "the property of being a couple". This denotation applies straightforwardly to conjunctions of count or concrete nouns. However, the conjunction of count nouns is not the most widespread pattern of CCA compared to other possible combinations. In (18) we enumerate some, if not all, possible types of singular conjoined nouns that denote pluralities and therefore take plural agreement on the verb when they are (preverbal) subjects; recall that "plural agreement is required when the conjunction operation is interpreted as group formation" (Lasersohn 1995: 111, after Hoeksema 1983). (18a) illustrates the split interpretation with (concrete) count nouns. (18b) exhibits the conjunction of mass nouns. In (18c) we
find a coordination of two collective nouns, in (18d) one of abstract nouns. In (18e) the
conjunction of nominalizations shows up. In our structures, then, the conjunction
denotes a set of atomic or non-atomic individuals.

(18) a. [Su madre y hermana] hablaron con él.\(^{[20]}\)

his.SG mother.F.SG and sister.F.SG talk.PST.3PL to him

‘His mother and sister talked to him.’

b. [La arena y tierra afectadas] son cuidadosamente

the.F.SG sand.F.SG and soil.F.SG affected F.PL be.PRS.3PL carefully

removidas… \(^{[21]}\)

turned over

‘The sand and soil affected are carefully turned over…’

c. [La marinería y tropa] deben tener dos mudas de flanel.\(^{[22]}\)

the.F.SG crew.F.SG and troop.F.SG should.PL have two changes of flannel

‘The ship’s crew and troops should have two changes of flannel clothing.’

d. [La confianza y seguridad] aumentan y aparece euforia…\(^{[23]}\)

the.F.SG trust.F.SG and confidence.F.SG increase.PRS.3PL and appears euphoria

‘Trust and confidence increase and euphoria appears…’

e. [La maduración y putrefacción] suceden casi paralelamente.\(^{[24]}\)

the.F.SG ripening.F.SG and rotting.F.SG occur.PRS.3PL almost in parallel

‘The ripening and rotting take place almost in parallel.’

A qualification regarding the data in (18a) is in order. Camacho (1999: 2655) claims
that “when two concrete names coordinate [sharing the determiner] the result only refers
to one object with the properties designated by the two nouns”;¹⁰ that is, according to this author cases like (18a) should have a joint reading (see also Camacho 2003: 130). Our claim is that even if it is true that the pattern in (18a) is less productive, not all cases of coordination of concrete / count nouns have a joint (versus a split) reading; recall (2), and observe examples in (19):

(19) a. *Dio el teléfono y dirección del procesado.* [²⁵]
    give.PST.3SG the.M.SG telephone.M.SG and address.F.SG of the defendant
    ‘He gave the defendant’s telephone number and address.’

b. *Algunas basas de la cabecera y crucero*
    some column.bases of the.F.SG front.F.SG and transept.M.SG
    van recorridas por una cenefa.[²⁶]
    go.PRS.3PL covered by a frieze
    ‘Some column bases of the front and transept are decorated with a frieze.’

c. *Se quitó el abrigo y bufanda azules.*[²⁷]
    SE took.off.PST.3SG the.M.SG coat.M.SG and scarf.F.SG blue.PL
    ‘He took of his blue coat and scarf.’

We will leave open here the question of whether the more reduced productivity of split readings with concrete count nouns (especially with animate ones) is simply a pragmatic effect or whether it must be attributed to other factors.

---

¹⁰ See also King & Dalrymple (2004).
2.3.1. Group and distributed readings

As is the case with other instances of plural denoting phrases, DP internal N-y-N conjunctions give rise to distributive as well as to collective readings. Put in other words, conjoined Ns can denote individuals or can have a group reading. Following Lasersohn (1995), we assume (although this is not crucial) that collective and distributed readings depend entirely on the predicate with which such noun phrases combine. With distributive predicates (hablar francés ‘speak French’, aumentar por separado ‘increase separately’) in examples like Su madre y hermana hablan francés ‘His mother and sister speak French’, La confianza y seguridad aumentan por separado ‘Trust and confidence increase separately’ the event denoted is predicated individually of the elements forming the conjunction. On the other hand, the collective reading is also available for the coordinations in (18). Different syntactic contexts (set forth by Aoun, Benmamoun & Sportiche 1994) forcing the group reading of coordinate count nouns are illustrated in (20): (20a) co-appearance with verbs requiring semantically plural subjects such as reunirse, encontrarse (‘meet’, ‘gather’); (20b) acceptance of similarity predicates or combination with the adjective junto/a (‘together’); (20c) binding of reciprocals; or (20d) respectively coordination, namely, cases where respectivamente (‘respectively’) sets-up a one-to-one mapping between two sets (Munn 1993: 8). These examples indicate that the coordination of Ns has a cumulative reading and a logical form in which the individuals must be seen as acting together or being a group:

(20) [Su madre y hermana]
his.SG mother.F.SG and sister.F.SG

a. se {reunieron / encontraron} ayer.

SE {gather.PST.3PL / met.PST.3PL} yesterday

‘met yesterday.’

b. {son parecidas / vinieron juntas}.

be.PRS.3PL similar.F.SG / come.PST.3PL together.F.SG

‘resemble each other / came together.’

c. se quieren (la una a la otra).

SE.RECP love.PRS.3PL the.F.SG one.F.SG to the.F.SG other.F.SG

‘love each other.’

d. se comieron la tarta y los bollos, respectivamente.

SE eat.PST.3PL the cake and the cookies respectively

‘ate the cake and the cookies, respectively.’

The series in (21) provides examples of contexts which show that coordination of mass, collective and abstract nouns have properties similar to those of count terms: they have plural reference and show both distributed and collective interpretations. (21a) illustrates occurrence with predicates of distribution like distribuirse, esparcirse (‘distribute’, ‘spread out’); (21b) and (21c) illustrate occurrence with the predicates mismo (‘same’) and diferente (‘different’), which are usually licensed by semantic plurals, although mismo triggers a group reading and diferente a distributed reading. Example (22) shows that mass nouns also allow for reciprocals:

(21) [La arena y tierra] / [La marinería y tropa] /
The examples in (20) through (22) show that the coordinated structures in question are semantically plural even though the DP is headed by a singular determiner. An interesting syntactic corollary of (20), (21) and (22) is that DP-internal N-y-N conjuncts cannot be considered the result of clausal coordination, that is, the result of a conjunction of underlying sentences. The coordination of sentences like *La madre se reunió (‘The mother met’) and *La hermana se reunió (‘The sister met’) or *La madre es parecida (‘The mother is similar’) and *La hermana es parecida (‘The sister is...

11 It is true that La arena se esparció, La tropa se distribuyó are also grammatical, differing in this sense from the previous example *La madre es parecida (the discourse-linked reading of the adjective, where a null complement is understood, must be discarded). However, the occurrence of conjuntamente (‘together’) in (21a) coerces the plural reading of the conjunction even if the individual nouns each have a collective reading.
similar’) is either uninterpretable or ungrammatical. In other words, in Spanish, group predicates like similar, meet or together require both syntactic and semantic plurality, something that cannot be accounted for if we propose that sentences like the ones in (18) and (19) are an external manifestation of underlying clausal coordination. These facts suggest that the origin of the plural reading is located in the conjunction of Ns and not in the coordination of sentences that, through a mechanism of conjunction reduction (based on ATB movement and right node raising), produces the surface coordination of NPs, as proposed by Aoun, Benmamoun & Sportiche (1994, 1999) for the analysis of CCA in V-S structures with coordinated subjects in Arabic (see Munn 1999 for arguments against this analysis).

3. The underlying structure of conjoined Ns

Having described in the last section the patterns of agreement found inside DPs with a conjunction of Ns, we want now to propose a syntactic analysis for such a structure. Let us simply recall that in this structure any determiner and prenominal adjective agrees in singular number (also in gender) with its closest conjunct, the first noun of the coordination. Postnominal adjectives may agree in singular number (also in gender) with the N immediately to their left. Such an option alternates with full plural agreement (and gender resolution). To account for this generalization in an explanatory fashion we will proceed in two steps. First in § 3.1 we will propose and justify that the structures we are considering are instances of DPs containing a Conjunction Phrase [CoP]. This position taken, we will then show that coordinated phrases are not superficial constituents resulting from an ellipsis process. This point will be argued in § 3.2.
3.1. A CoP analysis for coordinated NPs

The usual analyses of coordinated structures in the generative tradition assert that the head Co (y ‘and’) projects a Coordination Phrase [CoP] in which the two members of the conjunction stand in an asymmetric relation (Munn 1993, 1999, Kayne 1994, Johannessen 1996, 1998, Progovac 1998, Camacho 2003). In such a CoP the first conjunct occupies a higher c-commanding position with respect to the second, as in (23):\(^{12}\)

\[
(23) \quad [\text{CoP } N \ [\text{Co'} \ \text{and} \ N]]
\]

An argument for asymmetry between Specifier and Complement in CoPs is provided precisely by the existence of unbalanced agreement in coordinate structures, that is, cases where an external head agrees with only one of the conjuncts. If one of the conjuncts is hierarchically higher than the rest of the CoP this will provide an explanation, for instance, for the fact that in certain languages the verb agrees only with the first conjunct when a coordinate subject appears postverbally (see also van Koppen 2005 for V-Comp agreement in Dutch dialects). In the set of data we are considering we also seem to have an instance of unbalanced agreement: D agrees in singular only with the first member of the coordination. In parallel, TP agrees in plural with DP when it is a subject, i.e., the DP triggers plural agreement in verbs and also in other types of

---

\(^{12}\) This approach faces a number of problems, as has been noted by Borsley (2005). These problems relate to various aspects of conjoined phrases, for instance, the not always homogeneous content of the feature shared by both conjuncts that should percolate up to CoP or the non-maximality of the conjuncts. The facts we are considering in this article present a problem, though, for a symmetric analysis.
predicates. To account for this complex pattern, we consider it necessary to assume an asymmetric analysis for the Spanish coordinated structures giving rise to CCA. To explain these facts, a modification of the theory of features will also be necessary (see § 4).

Two different structures have been suggested in the literature to represent an asymmetrical relation between conjuncts. These two structures are shown in (24a) and (24b) (from Munn 1999: § 4):¹³

(24) a. CoP  \[\text{XP}_1 \text{Co'} \text{XP}_2\]  
    \[\text{Co} \quad \text{and} \quad \text{XP}_2\]  

b. \[\text{NP}_1 \text{BP} \text{NP}_2\]  
    \[\text{B} \quad \text{and} \quad \text{NP}_2\]

In the first structure, (24a), the head of the phrase is the conjunction, and the first and second conjuncts occupy the specifier and complement position of CoP, respectively. In (24b) the head of the conjoined noun phrase is the first conjunct and the second one is part of a Boolean phrase, BP, adjoined to it. In both cases the first conjunct is accessible to c-command.¹⁴ We will assume (24a) as the best possible structure to explain CCA within DPs, since (24b) would run into difficulties to explain how the phi-features of both conjuncts percolate up to the CoP level (i.e., how number and gender resolution is triggered), a derivational step that will be crucial in our proposal to explain the agreement patterns described above. We thus take (25) as a point of departure for our analysis of CCA.

¹³ (24b) is taken from Munn (1999: 663). See Lorimor (2007) for a revision of these proposals.
¹⁴ There is a third possibility, posed by Kayne (1994), which is: the Specifier is left-adjoined to the CoP.
The reasons for this choice will become clearer in the following section where we work out all the aspects of Agree and c-command in CCA processes.

We assume a DP structure without additional functional projections (such as NumberP, GenderP or ClassifierP), that is, we claim that agreement inside the DP can be explained without appealing to dedicated functional nodes for number (and gender) (see Alexiadou, Haegeman & Stravou 2007 for a review of the main proposals regarding functional projections inside DP).

It is important to note that, in (25), prenominal adjectives are projected not inside the nominal projection (Bernstein 1993) but in a functional projection above CoP. We take no particular side in the debate about whether adjectives merge successively in an ordered set of specific functional projections (Cinque 1994) or are instead attached to independently motivated functional projections (Demonte 2008, Svenonius 2008). We also do not take any side as to the specifier or adjunct status of the APs in prenominal position.\(^{15}\) As for postnominal adjectives, we assume that they are generated inside a reduced relative clause, as we will describe in section 5.1.1.

\(^{15}\) Nevertheless, it is worth wondering whether an adjunction analysis of attributive prenominal adjectives might not help to better explain the data we are considering. In fact, in a recent interesting proposal, Schoorlemmer (2009) argues for the adjunct condition of attributive adjectives. If adjectives are adjuncts,
The last issue to be addressed in order to justify the representation in (25) is that of the level of projection of the conjuncts. In fact, if they are Specifiers and Complements as we have argued they must be maximal projections (see Borsley 2005 on this theoretical point). In the examples we have presented thus far, we have shown simple coordination of nouns, i.e., apparent non-maximal projections. Yet, we would like to claim that CoP is a coordination of NPs; in the following subsection, when arguing against the ellipsis analysis, we will go deeper into this issue. For the time being, let us simply observe that sentences such as the ones in (26) where each of the conjoined nouns takes its own complement provide straightforward evidence for the NP condition of the conjuncts:

(26) a. La reciente [venta de armas y compra de uranio]

están dañando su imagen.

‘The recent arms sale and purchase of uranium are damaging his image.’

b. El [teléfono de Luisa y dirección de Pedro]

están en mi agenda.

‘Luisa’s phone number and Pedro’s address are in my diary.’

It should be possible to establish dominance and not c-command as the structural condition for the Agree operation. Actually, the dominance requirement makes it possible to correctly derive the structures with strong and weak agreement in Germanic. However, as Schoorlemmer notes (2009: 243), there is no empirical motivation in Romance for a choice between the c-command or the dominance requirement, even if one accepts that this latter approach could be theoretically simpler. In consequence, we will stand by the standard view of Agree as c-command and not make a specific case for the adjunct or specifier condition of prenominal adjectives.
Problematic for this view are the sentences in which a single PP complement following $N_2$ refers to both of the conjuncts, as in (19a) above. We claim that these kinds of examples could be treated as cases of some version of right node raising applying within the DP (we use this term merely descriptively; we will not attempt to spell out a syntactic analysis of these examples in terms of rightward movement, deletion or multidominance). Borsley (2005) leaves open the possibility of analysing parallel examples like *The King and Queen of France* as right node raising structures; Sabbagh (2007) treats examples like *Jamie read [a short review, and two longer reviews] for the same journal, of my recent book* as instances of ATB rightward movement of the PP complement of the conjoined nouns.\(^\text{16}\)

3.2. Arguments against an ellipsis analysis

In this section we will review the ellipsis-based account developed by Camacho (2003: § 2.5.3) for the types of DP under study.\(^\text{17}\) Camacho (2003: 131) claims that the structure of examples like (27a) and (28a) involves full DP conjunction and licensing of null structure in the second DP under identity with parallel elements in the first DP, as

\(^{16}\) Note that a postnominal adjective, either singular or plural, may also be present between $N_2$ and the PP, (i). In this case, the PP obligatorily follows the adjective. The opposite order results in agrammaticality (unless the adjective is built as an appositive or incidental constituent). Although the ordering between postnominal adjectives and PPs in Spanish non-coordinated NPs depends on a complex set of factors (see Demonte 1999a: § 3.3.1.1, § 3.5.1.2), it is possible to find pairs like (ii). However, in the case of coordinated NPs, only the order A-PP is possible. If postnominal adjectives are base-generated above the position where nouns and their PP complements are generated, this would be an indication that the PP appears in a derived position in these examples.

\(\text{(i)}\) \begin{align*}
  \text{La venta y compra } & \text{[rápida/rápidas] de uranio.} \\
  \text{the.F.SG sale.F.SG and purchase.F.SG rapid.F.SG/F.PL of uranium} \\
  \text{‘The rapid sale and purchase of uranium.’}
\end{align*}

\(\text{(ii)}\) \begin{align*}
  \text{La compra de uranio rápida – La compra rápida de uranio} \\
  \text{the.F.SG purchase.F.SG of uranium rapid.F.SG – the.F.SG purchase.F.SG rapid.F.SG of uranium}
\end{align*}

\(^{17}\) See section 5.1.2 for discussion of ellipsis-based analyses of postnominal adjectives in the structures in question.
illustrated in (27b) and (28b) (Chaves 2008: 270 suggests a parallel analysis of examples like *That boy and girl are really no different from each other;* Cinque 2010: § 7.3 also suggests this kind of analysis for examples parallel to (28a)).

(27)  
a. *La flora y relieve (me sorprendieron mucho).*  
‘The flora and rugged landscape (astonished me).’

b. \([\text{DP}_1 \ D \ N] \ y \ [\text{DP}_2 \ \emptyset_D \ N]\)

(28)  
a. *La fascinante flora y relieve (me sorprendieron mucho).*  
‘The fascinating flora and rugged landscape (astonished me).’

b. \([\text{DP}_1 \ D \ A \ N] \ y \ [\text{DP}_2 \ \emptyset_D \ \emptyset_A \ N]\)

The ellipsis analysis can explain the following facts: (a) the plural denotation of these sequences and the agreement triggered on the verb, since two full DPs are being conjoined; (b) the scope of the adjective *fascinante* in (28a), since there would be two instances of *A* in the structure; and (c) the fact that *D* compulsorily agrees with the first noun of the coordination. However, there are various questions that cannot be easily addressed and answered under the ellipsis analysis.

First, ellipsis analyses cannot explain the fact that a hypothetically elliptical sentence has a quantificational reading that its non-elliptical counterpart lacks. Consider the examples in (29) and (30). If we set up a context in which there are two boys and two girls, in (29), a total of four balloons are being carried (each of the two boys carries a balloon and each of the two girls carries a balloon). The example in (30) can have the same meaning but additionally permits the interpretation that a total of only two balloons is being carried (each of them carried by a pair consisting of one boy and one
girl). If it is assumed, as generally claimed in the literature, that ellipsis processes do not add readings to non-elliptical structures, this set of facts suggests that the pair interpretation of the sentence in (30) derives from a non-elliptical structure.

(29)  
\[
\text{Cada niño y cada niña llevan un globo.}
\]
\[
\text{each.SG boy.SG and each.SG girl.SG carry.PRS.3PL a balloon}
\]

(30)  
\[
\text{Cada niño y niña llevan un globo.}
\]
\[
\text{each.SG boy.SG and girl.SG carry.PRS.3PL a balloon}
\]

Second, Camacho’s analysis would need some stipulation to explain why, in DP$_2$, the noun must be obligatorily a remnant of the ellipsis process. If, according to the ellipsis approach, D and A in DP$_2$ can be elided under identity with D and A in DP$_1$, why can N in DP$_2$ not be elided under identity with the N in DP$_1$? Observe that in an example like (31a) the conjunction cannot refer to two different women—the split reading—but can only refer to a single woman who is married both to Pedro and Juan—the joint reading. Yet, the split reading would be the expected interpretation if the structure of this example involved an ellipsis process of D, A and N in the second conjunct under identity with D, A and N in the first conjunct, as in (31b):

(31)  
\[
\text{a. La hermosa mujer de Pedro y de Juan (*vendrán el lunes).}
\]
\[
\text{the.F.SG beautiful.F.SG wife.F.SG of Pedro and of Juan (arrive.FUT.3PL the Monday)}
\]
\[
\text{(intended: ‘The beautiful wife of Pedro and the beautiful wife of Juan will arrive on Monday.’)}
\]

\[
b. \ast \left[\text{DP}_1 \ D \ A \ N \ \text{PP}\right] \ y \left[\text{DP}_2 \ \varnothing_D \ \varnothing_A \ \varnothing_N \ \text{PP}\right]
\]
It is also important to note that in our structures, contrary to what happens generally in coordinate structures where ellipsis has been applied, N₂, the remnant of the ellipsis process, does not receive a special interpretation from the point of view of information structure (for example, a contrastive interpretation).¹⁸

These empirical issues aside, a theoretical question remains with respect to the status of (27b) and (28b) as cases of phrasal or head ellipsis. If this process is to be understood as a case of phrasal ellipsis, then the fact that it affects non-constituents must be explained; note that in (28b), D and A in the second conjunct do not form a syntactic constituent. As is generally claimed in the generative literature, phrasal ellipsis only affects segments which are syntactic constituents (Lobeck 1995, Merchant 2001, Johnson 2004 and others).¹⁹ The second possibility is to understand the ellipsis process in (27b) and (28b) as head ellipsis. This kind of approach would again face serious problems. On the one hand, head ellipsis—once its existence is admitted and whichever way it is implemented—is constrained by severe conditions; one of these conditions is

---

¹⁸ The fact that, as shown in (i), two adjectives can appear in these structures, each of them modifying N₁ and N₂ respectively, does not lead to the DP coordination analysis either. It is important to note that this possibility is extremely frequent in DPs with a joint reading, as in (ii). These data seem to indicate that the nominal projections conjoined are not DPs but the projections hosting the adjectives in these cases.

(i) a. This old man and young woman fell in love.
   b. Su mala puntería y peor fortuna habían dejado el resultado en un preocupante 0-0. ²⁴¹
   ‘His bad aim and worse fortune had left the score a worrying 0-0.’

(ii) ... Manuel Cortés, un experimentado observador y excelente fotógrafo.²⁴²

¹⁹ In order to maintain a phrasal ellipsis approach to the phenomenon we are studying and, at the same time, overcome this problem, the analysis in (27b) and (28b) could be recast as follows (see for example the analysis of Nthelitheos 2004 on nominal ellipsis). Assuming a structural approach to ellipsis (for example, of the kind adopted in Merchant’s works) it could be claimed that the ellipsis process that underlies an example like (28a) takes place in two steps, (i): (a) movement of N₂ out of the second DP (N₂ would then be the remnant of the ellipsis process), and (b) deletion/non-pronunciation of the phonological features of the whole DP₂ (containing D, A and the trace of N).

(i) [{CoP [{DP₁ la fascinante flora} [Co y [XP relieve [el fascinante t]]]]}

However, this analysis would have to motivate what the target position of the displaced constituent is. Nor can it easily account for the facts described in (31) in the text. The reasons for ruling out a structure like (ii) are also unclear under this kind of approach.

(ii) [{[DP₁ la hermosa mujer de Pedro] [Co y [XP de Juan [la hermosa mujer t]]]]
adjacency between the elided head and its antecedent head (see Saab 2009). However, in our structures, there is no adjacency between D₂ and D₁. On the other hand, in the case of adjectives, note that the adjectival projection can be a phrase, (32), and thus cannot be affected by head ellipsis.

(32) *Este hecho merece mi más enérgica reprobación y repulsa.*[28]

This fact deserves my firmest censure and condemnation.

Although the ellipsis approach could be amended or reformulated to explain the aforementioned facts, in the light of the facts and arguments set out in the preceding discussion, we conclude that it is worth exploring an account of the agreement pattern under study in terms of Closest Conjunct Agreement. Moreover, the basic assumptions of our analysis have been independently motivated in the literature and can account for a larger set of data.

4. The analysis of CCA: Agree and feature checking within DP

4.1. Basic assumptions. Agree, Probes and Goals

In this section we will present a Minimalist view of CCA within a theory of feature matching/valuation based on the syntactic mechanism Agree (Chomsky 2000, 2001, 2004, 2008). We take as our point of departure the definition of Agree in (33) (from Bhatt 2005: 758):
Agree is the process by means of which a head $X^0$ with unvalued uninterpretable features (the Probe) identifies the closest $Y^0/YP$ in its c-command domain with the relevant set of visible matching (i.e., non-distinct) interpretable features (the Goal) and uses the interpretable features of $Y^0/YP$ to value its uninterpretable features.

The operation Agree is constrained (apart from locality and intervention conditions) by the \textit{maximization principle} (Chomsky 2001), which states that if the Probe and the Goal match, their unvalued features must be eliminated at once, as fully as possible. This condition on Agree will have crucial consequences for our proposal.

We will adopt this basic framework with the two important modifications introduced by Frampton & Gutmann’s (2000, 2006) theory of \textit{Feature Sharing}: (i) the features of the Goal need not be valued in order for a Probe to agree with them and (ii) an element containing only valued features can act as a Goal in the derivation (thus doing away with Chomsky’s \textit{Activation Condition}). Let us briefly present this model, according to which, Agree is best seen as a feature-sharing rather than a feature-copying operation.

In line with Chomsky (2001) and many other approaches to the syntactic nature of agreement, Frampton & Gutmann (2000, 2006) assume that lexical items can enter the derivation with their features either valued or unvalued. Unvalued features must be valued before the derivation is transferred to the interfaces, otherwise it would crash. Agree is the syntactic operation established between a Probe containing unvalued features that need to be assigned a value and a Goal with matching counterparts. The
Probe conducts a top-down search within its c-command domain seeking a feature, be it valued or unvalued, that matches its own unvalued feature (matching is independent of valuation). When this is accomplished, the top-down search stops and the unvalued feature on the Probe and the feature on the Goal are coalesced, resulting in a shared feature, even if agreement does not succeed in valuing at that point the unvalued feature of the Probe. In that case, the Probe and the Goal will share an instance of an unvalued feature, which will be valued at once, in a later step of the derivation. In this model, unvalued features are not deleted following Agree. They remain present in all nodes in which the features are shared. Interface conditions determine where each feature is interpreted.

In this context, we would now like to describe the facts presented above in terms of Probes and Goals. We observed, in the first place, that the first noun in the DP internal coordination determines agreement on prenominal adjectives and determiners (CCA). We observed, on the other hand, that both CoP and N2 seem to be able to determine agreement on the adjective when this element appears postnominally, and there seems to be no semantic or morphological motivation for such optionality (we will postpone until section 5.2 the discussion of this second pattern). Thus, N1, CoP and apparently N2 are Goals for agreement relations, and D and A are Probes that seek to be determined. Moreover, CoP seems to determine the agreement relation with a TP Probe and triggers plural subject-verb agreement independently of the CCA facts inside DP.

Various important questions arise at this point that we would like to deal with in the remaining part of this section: a) What valued and unvalued features are at stake in the phenomenon under scrutiny? b) What is the feature specification of the heads D, N and Co(P)? c) How does c-command work in these cases and why do, in the CCA
pattern, D and (prenominal) A agree only with N₁, not with N₂? d) Finally, how can we explain the paradoxical fact that in all the sentences we are considering D and pronominal A have singular form, as the result of CCA, but the DP receives a plural interpretation, as shown by the fact that, when it is a subject, it is able to match the unvalued number features of T and value them as plural (see (2), (4), (7), (18))? 

4.2. Two types of features

In the PP/Minimalist tradition it has always been assumed that syntactic agreement operates with phi-features. However, the notion of the phi-feature set, as generally understood, is insufficient to explain the facts described here, particularly the paradox we have just noted. Our proposal is that the theory of phi-features must be enriched, and we would like to propose a hypothesis that is able to capture the transmodular relevance of phi-features. Specifically, we claim that two different sets of phi-features must be introduced in the Minimalist syntactic model. Borrowing terminology from the HPSG tradition, we will call them *concord phi-features* and *index phi-features*. Concord phi-features are formal features related to the morphosyntactic/declensional properties of lexical items and codify instructions to the PF interface. Index phi-features are formal features related to semantic properties of lexical items and codify instructions to the LF interface. The proposal that two distinct sets of features are involved in agreement processes has been developed in the OT framework (Badecker 2007, specifically with regard to CCA), and also in the LFG and HPSG models (Pollard & Sag 1994, Kathol 1999, Wechsler & Zlatić 2000, 2003, King & Dalrymple 2004, Villavicencio, Sadler & Arnold 2005—the latter two with specific regard to CCA—and others) (also in semantic
approaches to phi-features, Sauerland 2008). Data supporting the hypothesis that nouns carry two sets of agreement features come from the mixed agreement patterns triggered by collective nouns in some languages. Collective nouns in English (e.g., band) and Spanish (e.g., gente ‘people’, pareja ‘couple’, etc.) give rise to mixed agreement patterns (*This*SG *band*SG *are*PL *absolutely* amazing – Wechsler & Zlatić 2003: 76–; *Esta*F.SG *gente*F.SG *nos* estánPL *masacrandar*29) ‘These people are slaughtering us’). The idea that two distinct sets of agreement features co-exist in the same node is also present in a few works within the PP/Minimalist tradition. D’Alessandro (2004a, 2004b) claims that sigma features must be added to the set of phi-features to account for agreement in impersonal *si* constructions. Similarly, in Costa & Pereira (2005) an additional set of referential (phi) features is proposed to explain the agreement patterns which the Portuguese pronoun *a gente* (‘we’, lit. ‘the people’) gives rise to. López (2007) also posits within the minimalist framework that lexical items (specifically, nouns) contain a semantic feature matrix and a morphosyntactic feature matrix to explain, among other empirical facts, agreement in indefinite *se* constructions or quirky subject structures in Spanish. Recently, Danon (2011) claims that the Minimalist feature theory, as it is generally used, is too restrictive, and proposes that nouns and quantifiers have concord and index features in order to account for the agreement patterns triggered by partitive DPs in Hebrew (also Heycock & Zamparelli 2005 make use of syntactic and semantic plural features to account for data parallel to what we are describing).

4.2.1. Featural content of N, D and CoP
In this subsection, we will examine the featural content of the different categories involved in the derivation of the structures under study. We will use example (7a) (la fascinante flora y relieve) as an illustration. Following Wechsler & Zlatić (2000, 2003), we assume that nouns have c(oncord) and i(ndex) phi-features. C-features reflect morphological properties of nouns, namely gender, number and Case. According to these authors, nouns are also associated with indices that reflect semantic properties of nouns and are conceived as feature structures (i-features: gender, number and person). Gender is associated with sex or other semantic categorization of the entities denoted by the noun, number with cardinality and person with the identification of participants. We claim that nouns enter the derivation with a double set of phi-features. The first part of this double set consists of a bundle of c-features, including gender, number and Case. With regard to Case, we assert that all nouns have an abstract Case feature, though it is not phonologically visible in Spanish nouns—as opposed, for example, to Serbo-Croatian, Greek or Russian. Person is absent from this set, since it is not a declensional category of Ns. The second part of the double set consists of a bundle of i-features, including gender, number and person. We thus claim that ‘person’ is considered a semantic property of nouns. This idea is supported by the fact that person specification (first, second person) seems to be contingent on or to interact with the property of being animate/human, which is undoubtedly a semantic property of nouns (see the contrast in (34)), which suggests that animate/human nouns may trigger various forms of person agreement (34a), while inanimate nouns do not (34b). C- and i-features are valued in N, except for the Case feature in the c-set.

---

20 See Demonte, Fernández-Alcalde & Pérez-Jiménez (in press) for a full exposition of this hypothesis.
According to our proposal, the feature bundles of the nouns *flora* and *relieve* (from example in (7a)) are made explicit in (35). Note that the gender and number features have equivalent values in the *c*- and *i*-bundles.21

Let us now consider determiners and adjectives. We follow Wechsler & Zlatić’s proposal that determiners and adjectives carry gender, number and Case *c*-features, linked to the morphology of these categories. These features are all visible in D; however, the Case feature remains phonologically non-visible in Spanish adjectives differing in this regard from languages such as German or Greek, in which adjectives carry explicit Case markers. Our claim is that D also carries gender, number and person *i*-features. Adjectives do not have *i*-features. Both sets of features are unvalued in D since it is a functional category. The featural make-up of D is thus (36), while the

---

21 The gender index feature is semantically interpreted as sex in the case of nouns like *esposa*, *hijo* (‘wife’, ‘son’). For the relation between concord gender features, index gender features and semantic interpretation in the case of inanimate nouns or animate non-sexed nouns (that is, nouns grammatically unmarked for sex), like *persona*, see Wechsler & Zlatić (2003: § 4.1, § 4.2) and López (2007:§ 2.6). We will not concern ourselves with this issue further in this paper.
featural make-up of A is (37). The intuition behind the proposal that D carries \(i\)-features is that D ‘collects’ the valued \(i\)-features of the noun via agreement. This relation can be taken as the basis for the semantics of the determiner: D operates on the noun’s index and maps it to some item in the semantic model (for example, in the case of referential DPs, the \(i\)-features of the noun constrain the range of possible referents of the DP).

Agreement between D and N(P) also makes it possible for the DP as a whole (via its head D) to carry all the phi-features with which external heads agree.

\[
(36) \quad D \quad i[G( ) \ N( ) \ P( )] \quad c[G( ) \ N( ) \ C( )]
\]

\[
(37) \quad A \quad c[G( ) \ N( ) \ C( )]
\]

The question we must now answer is the following: what is the feature structure of a coordination of nouns? In coordinate structures like (7a) (*la fascinante flora y relieve*), see (38), both N(P) conjuncts have \(c\)- and \(i\)-features. The coordinate phrase, nevertheless, lacks \(c\)-features. Remember that \(c\)-features are related to the declensional properties of lexical items and, in this case, the head of the phrase, the conjunction \(y\), is not morphosyntactically marked as plural or singular, masculine or feminine. The coordinate phrase, however, bears \(i\)-features (on this idea, see also Dalrymple & Kaplan 2000, Wechsler & Zlatić 2003, King & Dalrymple 2004, Badecker 2007 and others).

The proposal that CoP bears \(i\)-features receives its motivation from the semantics of *and* in group-forming coordinations: the conjunction semantically operates on the indices of its conjuncts, joining them (Zoerner 1995 and references therein). Since indices are understood as feature structures, the conjunction joins the \(i\)-feature bundles of N(P)₁ and
As a consequence, the coordinate phrase as a whole has a plural \(i\)-feature and gender and person \(i\)-features determined via resolution.\(^{22}\)

\[4.2.2. \text{Agreement in the prenominal field and Subject-Verb agreement}\]

\[\text{---}\]

\[22\text{ On this process, see Corbett (1991, 2006), and others.}\]
In this subsection, we will propose a unified analysis of the DP-internal facts illustrated in the preceding sections. We will make brief comments on Subject-Verb agreement, but we will leave some questions open since this is not the main issue of this paper. We will use example (7a) to illustrate our analysis.

To understand how the derivation proceeds at the stage captured in (39) it is important to remember that the operation Agree is constrained by the *maximization principle* (initially proposed by Chomsky 2001). According to this principle, if a Probe matches with a Goal, its unvalued features must be valued at once, as fully as possible; partial valuation of the features of a Probe under Match, followed by valuation of the residue under remoter Match, is not an option. This condition on Agree, which we incorporate into the framework of Feature Sharing, has crucial consequences for our proposal.

Let us first consider agreement of D, setting aside agreement of the adjective for the moment. In (39), D, with unvalued phi-features, probes for a Goal with their matching counterparts. Crucially for our analysis, *i*- and *c*-features are treated by syntax as bundles, as expected from the application of the *maximization principle* stated above: D’s *i*-features agree with the closest Goal containing another instance of this set of features, namely CoP; since the *i*-features of CoP are valued, the features of D receive their value.  

23 Although CoP and N₁ are equally local to the Probe D, according to van Koppen’s (2005: 14) notion of *equally local*, (i), (cf. also Chomsky’s (2000) definition of *equidistance*), we claim that CoP is the closest Goal for Probe D since *merge* takes place between D and CoP, and not between D and the specifier of CoP.

(i) Y and Z are equally local to X iff (i) X c-commands both Y and Z, and (ii) the set of nodes that c-command Y is identical to the set of nodes that c-command Z.
the theory of feature sharing since, as noted above, Agree is blind to feature values: it
just pairs up matching features. These DP internal agreement processes, usually referred
to as Concord, are derived in our approach from the application of Agree. As a result of
these agreement operations, D is morphologically singular, which constitutes the
phenomenon of Closest Conjunct Agreement, but ‘indexically’ plural. The Case feature
of D also remains unvalued. We assume that the features of D are visible at the DP level
and can be accessed for DP external syntactic operations, as illustrated in (40).

Let us briefly address at this point agreement between T and the subject DP. Our claim
is that T bears only a c-bundle which contains at least person and number features.
These are c-features on T, because they correspond to the morphological/inflectional
properties of the verb and are visible at PF (we remain neutral as to whether T has i-
features related to the event denoted; see Wechsler & Zlatić 2003: § 7.5.1 on this topic).
Once T is merged in the derivation, the unvalued c-features of T (person, number) probe

24 We do not address here the question of whether the goal of agreement is the head of the phrase or the
maximal projection (via feature ‘percolation’), although we adhere to the latter option consistently. This
must be kept separate from the resolution process by means of which the Co head takes the indices of its
conjuncts and creates a new one at the CoP level.
for a matching set of features, find the $i$-features of DP and agree with them. This agreement relation is possible given that $c$- and $i$-features are different kinds of features from the point of view of the interfaces they give instructions to, but are treated equally by syntax. Therefore, a $c$-bundle can agree with an $i$-bundle as long as they both contain the same featural content, as is the case in Subject-Verb (T) agreement. As a result of Agree between T and DP, the number feature of T is valued as plural, since its value comes from the $i$-feature of D.\(^{25}\)

Let us now consider agreement of prenominal adjectives in (39). As noted above before, A carries $c$-features. These features find their closest Goal in the $c$-features of N(P), establishing with them an Agree relation. The $i$-features of CoP are overlooked, as expected given the maximization principle.

\subsection*{4.2.3. C-command and the features in D and A}

Apart from the hypothesis of two types of features and the articulation of Agree under such a view, a question still remains relative to the specific properties of adjective agreement: Do both Probes, D and A, enter simultaneously into an agreement relation with the corresponding Goal in (39)? There are two possibilities in our view. First, we could propose that N serves as a Goal to the various Agree relations that constitute Concord (Carstens 2000, 2001: 154). In fact, a common assumption is that these agreement operations take place simultaneously and there are two instances of Agree

\(^{25}\) Since the study of Subject-Verb agreement in the structures under study is not the primary goal of this paper, we will not address here the question of Case assignment to the coordinate nouns. See Demonte, Fernández-Alcalde & Pérez Jiménez (in press) for the proposal that the Case feature of the coordinate nouns is valued not by means of copying the value of another Case feature already valued in a different head, but rather as an argument-marking strategy dependent upon Agree. In other words, Case is valued in the coordinate nouns (as nominative in our structures) as a by-product of the Agree relation established between DP and T.
occurring at the same time; there is *multiple agreement*. The alternative possibility is to postulate that in the cases where A is a Probe for its closest Goal, N(P)₁, once A has valued its c-features, it could become a Goal to be probed by D. This second option is more akin to Chomsky’s (2001) idea that Agree is a single one-to-one Agree operation.²⁶ Finally, we need to explain why neither D nor A probe N₂ even though this N is also in their c-command domain. The answer is that, given (39), N₂ is not an available Goal for D and A since N₁ is closer to both of them than is N₂.

5. Postnominal adjectives. Agree and linear adjacency

By showing that there is something more than Agree behind the facts of adjective agreement, this section seeks to explain the agreement pattern found with postnominal adjectives: postnominal adjectives, in the structures under study, show either full agreement (that is, agreement with the coordination phrase) or agreement with the rightmost conjunct (N₂). This pattern is observed across different semantic/morphological classes of adjectives. In our corpus of 4328 examples of postnominal adjectives modifying a conjunction of Ns we have found 1787 cases of adnominal predicative adjectives (Bolinger 1967)—*indirect modification adjectives* in Cinque’s (2010) terms, *intersective/restrictive adjectives* in other explanations—and 2541 cases of *relational adjectives*—classificatory and thematic or nationality

²⁶ A third possibility, proposed by Schoorlemmer (2009: § 3.1), is to think that adjective agreement is licensed indirectly as the by-product of the Agree-relations established by a higher Probe, instead of being the result of a direct Agree relation between A and the noun. This idea works together with the hypothesis that adjectives are merged as adjuncts and that only dominance and not c-command is relevant for agreement. Actually, in languages where adjectives do not agree with N, the hypotheses of Agree through dominance and adjective adjunction to NP appear to work. In such an explanatory approach adjective agreement needs to be stipulated as *indirect agreement*. Romance languages, where agreement holds across the board, do not make a case in favour of such a view and the c-command requirement seems to be enough.
adjectives in Cinque’s terms. From the statistical point of view, the differences observed between different classes of adjectives with respect to their singular (CCA with N2) or plural agreement (agreement with the coordinate phrase) in postnominal position are not significant. The results of the distribution of singular/plural agreement across the classes of adjectives mentioned above are shown in Table 3. We have restricted the sample, as we did in section 2.1, to those cases where the relevant DP containing the conjunction of Ns and the adjective is a subject that triggers plural number agreement on the verb, since, in these cases, the interpretation of the coordination of NPs is undoubtedly plural. The Chi-square test shows that there is no significant correlation between adjective number in postnominal position and the class to which the adjective belongs (p > .05). Accordingly, we will offer a unified account for different semantic/morphological classes of adjectives to explain the agreement pattern described.

*Table 3 Adjective number by adjective class*

In (41)-(45), minimal pairs from our corpus are provided to illustrate the alternation between singular and plural agreement for both kinds of adjectives. In the pool of postnominal predicative adjectives we find all the adnominal adjectives which can also appear as predicates of copular sentences: participles, qualifying (perfecto), temporal
(actual), locational (exterior), frequency (constante) and even focus and degree adjectives like absoluto (since in most cases both subclasses accept predicative uses). In the pool of relational adjectives we find ethnic or nationality adjectives (catalán) and classifying adjectives (acuático), which can also be used in certain cases as predicates of copular sentences:

(41) a. *el timbre y ritmo perfecto*

   ‘The perfect tone and rhythm.’

b. *una textura y brillo perfectos*

   ‘A perfect texture and shine.’

(42) a. *el modelo y sistema actual*

5.1. Postnominal adjectives: Agree

5.1.1. Our analysis

Cases of individual (intra-dialectal) variation in agreement, such as the alternation we are showing between singular and plural in postnominal adjectives modifying plural conjunctions in Spanish, are not easy to handle in formal approaches to natural languages. In this paper we do not aim to provide an explanation for the type of variation involved in such a pattern (see Adger & Smith 2010 in this regard) but simply try to place such an alternation within the general theoretical frame we are taking as a point of departure. In brief, we explain plural agreement assuming, as in Cinque (2010),
that there are two sources for adnominal adjectives in DPs. Prenominal attributive adjectives are APs generated as specifiers of the functional heads of the extended projection of NP (recall (25)), whereas postnominal predicative adjectives are generated inside a reduced relative clause merged in a high position inside the DP structure (Cinque 2010).\footnote{Alternatively, it could be assumed that postnominal `attributive-predicative’ adjectives are generated in a small-clause structure (Demonte 1999b, 2008, Gutiérrez Rexach & Mallén 2001, 2002, Truswell 2004) or in a PredP (Bowers 1993, 2001).} We claim that plural agreement is the output of syntactic Agree while agreement of the adjective with the second noun of the coordination is determined by factors which fall outside narrow syntax.

Let us look at the derivation of postnominal adjectives with a plural marking. The partial structure in (46) is the underlying representation for constructions similar to the ones in (41)-(45) with a plural adjective. Consider the example *La lengua y cultura catalanas* (the.F.SG language.F.SG and culture.F.SG Catalan.F.PL). The index-bundle of the CoP contains a plural number feature and a gender feature determined by resolution: \(i[G(f) \text{N(pl)} P(3)]\). The postnominal adjective is generated within a reduced relative clause. The surface order of postnominal adjectives, as represented in (46), is derived via movement of the lower section of the DP which contains the CoP to a position above the node hosting the relative clause.
As to agreement, the relation between A and CoP is mediated by PRO. The pronoun in the reduced relative clause and CoP are coindexed, that is, they are coreferential (PRO behaves as an *obligatory control PRO* that must be c-commanded by its antecedent; note that in (46) only CoP c-commands PRO –not N₁ nor N₂–). Since pronouns are nominal categories, they have index and concord phi-features. As to coindexed pronouns, their *i*-features (which determine anchoring conditions) must be semantically compatible with that of their antecedents; in other words, coindexing consists of sharing *i*-features (Wechsler & Zlatić 2003). Accordingly, PRO in (46) has the same index bundle as CoP: $i[\text{g(f) N(pl) p(3)}]$. With respect to the concord bundle of the pronoun, we will follow Wechsler & Zlatić’s proposal that there are linguistic constraints holding between concord values and index values, encoded grammatically in the form of a default feature structure for nouns and pronouns, according to which the gender and number values are identical in the concord and index bundles (though this constraint may be overridden by lexical exceptions; remember the cases of collective nouns such as Eng. *band* and Sp. *gente* ‘people’). Accordingly, in (46), the number and gender values of the concord bundle of PRO correlate with those of the index bundle (that is, feminine gender and plural number). Finally, as for the Case feature of the pronoun, let us assume that it is nominative (Cinque 2010: § 4.2) or null Case (Martin 2001 and others); nothing crucial hinges upon this. The Agree relation established in the reduced relative clause between the adjective and the pronoun results in the adjective showing up with plural number, and masculine gender. This is the outcome of syntactic agreement.
5.1.2. Is an ellipsis-based analysis an alternative?

Before turning to our proposal to explain agreement between postnominal adjectives and $N_2$, let us briefly consider and reject an alternative analysis of examples with (plural and singular) postnominal adjectives as cases of DP internal Right Node Raising [RNR] of the postnominal adjective. This kind of analysis would imply taking as a point of departure, contrary to what we have claimed in the text, the proposal that postnominal adjectives are generated in a low position inside each NP conjunct. Extending currently available analyses of Right Node Raising in verbal/sentential structures to our empirical domain, the following implementations of this alternative analysis would be possible. First, in an ellipsis/backward deletion account of RNR, (47a), the postnominal adjective would appear twice in the base structure, once under each NP conjunct. The first instance of the adjective is affected by ellipsis. Second, in an ATB rightward movement account, (47b), the adjective surfacing in postnominal position is rightwards ATB moved from each NP conjunct. Third, in a multidominance account, (47c), both $N_{P1}$ and $N_{P2}$ multidominate AP (we set aside the question of linearization in such structures).

\[(47)\]

a. $[DP\ D\ [CoP\ [NP_1\ N\ AP]\ [Co'\ [NP_2\ N\ AP]]]]$

b. $[DP\ D\ [CoP\ [N_{1P}\ N\ t]\ [Co'\ [NP_2\ N\ t]]\ AP]]$

c. $[DP\ D\ [CoP\ [NP_1\ N]\ [Co'\ [NP_2\ N\ AP]]]]$

The pros and cons of these analyses have been extensively discussed in the literature with respect to RNR in sentential contexts. With respect to our structures, and assuming that singular and plural adjectives are derived from the same structure, the ellipsis
account will encounter difficulties in explaining how the plural number (and resolved gender) of the postnominal adjective is derived, unless a stipulative constraint is posited according to which agreement in the second conjunct can be sensitive to deletion in the first conjunct. Moreover, the grammaticality of examples like (11) above (with collective/symmetric adjectives) cannot be explained in this analysis unless a covert semantic operation is proposed which allows the adjective inside NP₂ to scope over the coordination (see Abels 2004 for RNR in sentential contexts). Under the rightward ATB movement approach, the plural agreement of the adjective (and the gender mark determined by resolution) could be explained if it is assumed that agreement takes place in the final position occupied by the predicate in the derivation, a proposal with theoretical implications that we cannot explore here. Similarly, the presence of collective adjectives in postnominal position would be explained if scope is determined once the adjective has ATB moved. Finally, the multidominance approach, similarly to the ellipsis approach, would also have to resort to additional semantic operations to explain the presence of collective predicates in our structures. The plural number and resolved gender of the postnominal adjective could however be explained as a process of cumulative agreement, as proposed in Grosz (2009) for sentential RNR structures like (48) where, under a multidominance analysis, a shared agreement target (the T head) exhibits plural phi-agreement with two unshared agreement controllers (e.g., two subject-DPs), even if the latter are singular. This cumulative agreement is a type of agreement resolution that arises whenever a shared functional head agrees in phi-features with two singular unshared agreement triggers.
(48) [Sue’s proud that Bill have.PL has.SG traveled tBill/John to Cameroon.

The proposal presented in section 5.1.1 can explain without resorting to additional operations the scope of collective adjectives in the structures under study, as well as the plural number (and resolved gender) of postnominal adjectives, and can also be extended to explain plural agreement on the verb and other predicative elements in the sentence. However, even if it were proven that (at least some kinds of) postnominal adjectives (for example, relational adjectives) were generated inside the projection of each NP conjunct, and an analysis within the lines of ATB rightward movement or multidominance were to be assumed, the crucial observation is that agreement of postnominal As with N₂ in our structures cannot be derived in the syntax, that is, as the result of an Agree relation between A and N₂.

5.2. Postnominal adjectives. Linear adjacency

To explain agreement between postnominal adjectives and N₂ in the structures under study, we take as our point of departure the idea that in the mapping between syntax and phonology, there is an interface post-syntactic component—PF—where syntactic terminals are linearised and the feature bundles on which the syntactic component operates are replaced by vocabulary items and/or by agreement affixes (that is, by phonological strings). Assuming this approach, the fact that sometimes syntactic agreement does not surface with the expected morphological realization can be explained.
Recall that in the case of singular adjective agreement in our structures, agreement holds between the postnominal adjective and the rightmost conjunct in the CoP, although the adjective has scope over the two conjuncts. It is evident that singular agreement with the rightmost conjunct NP₂ is not anticipated by either of the two basic configurations proposed for adnominal adjectives. First, if the postnominal adjective is generated in the Spec of a functional phrase above CoP and postposition is the outcome of NP movement (Cinque 1994), CCA with the first conjunct N₁ and not with the second would obtain. Second, we have just seen that the reduced relative clause analysis of the postnominal adjective only gives rise to plural agreement (recall (46)).

Camacho (2003: 98-99) refers to cases of partial agreement of postnominal adjectives in coordinated DPs as *PF agreement structures* since, in these cases, "partial or full agreement does not necessarily correlate with differences in interpretation". His intuition—correct, from our point of view—is that partial agreement could obey non-syntactic factors. To be more explicit, we reject an explanation of singular agreement between postnominal adjectives and N₂ in terms Agree between the concord features of the postnominal adjectives and the concord features of N₂, because in the case of postnominal adjectives, agreement with N₂ (singular agreement) is not obligatory and, moreover, N₂ cannot be a Goal in any case. Our claim, thus, is that agreement of the postnominal adjective with the second conjunct is not a matter of syntax, since syntax deals with local hierarchical relations, but rather a matter of other locality conditions, namely, linear adjacency in a post-syntactic component. We assume that at PF precedence relations between syntactic constituents are established, that is, *linearisation* applies. When a DP structure of the kind we are studying is sent to PF, its internal elements are linearised in such a way that the rightmost N of the coordination (N₂)
precedes and is adjacent to the postnominal AP. This adjacency relation makes agreement between the adjective and N₂ possible.

Our proposal follows the spirit of Marušič, Nevins & Saksida (2007, 2011) and specifically Benmamoun, Bhatia & Polinsky’s (2010) explanation of CCA in Subject-Verb structures with coordinated subjects in head-final languages. In these languages, CCA is established between V/T and the rightmost conjunct of the coordinated subject. (49) shows partial number agreement between V/T and absolutive coordinated subject in Tsez; the verb agrees in singular with N₂—singular agreement shows up with no explicit number marking on the verb.28

\[(49) \quad \text{kid-no} \quad \text{uži}-n \quad \varnothing-ik’is\]

\[
girl.ABS.II-and \quad boy.ABS.I-and \quad I-go.PST
\]

‘A girl and a boy left.’ [Benmamoun, Bhatia & Polinsky 2010: 71 (12a)]

As the authors note, a purely syntactic account based on the asymmetric structure of the coordination (recall 24a) cannot account for CCA in these cases, since N₂ is structurally lower than N₁ and CoP, and thus cannot enter in an Agree relation with T. According to their \textit{compositional approach to agreement}, T agrees with CoP in the syntax, but this relationship can be satisfied at PF by spelling out the features of either CoP or the linearly closest conjunct, N₂, depending on many factors that remain to be studied. The consequence is that the way agreement features are spelled-out "may not be faithful to the syntactic component". In the same spirit, Borsley (2009) claims that adjacency

---

28 In this language, full plural agreement is also possible between V/T and the absolutive coordinate subject.

\[(i) \quad \text{kid-no} \quad \text{uži}-n \quad b-ik’is\]

\[
girl.ABS.II-and \quad boy.ABS.I-and \quad IPL-go.PST
\]

‘A girl and a boy left.’ [Benmamoun Bhatia y Polinsky 2010: 71 (11a)]
based on linear order determines agreement in Welsh, and partially determines agreement relations in other languages. In Polish, for example, when a coordinate subject follows the verb, the verb may agree with either the whole subject or merely the first conjunct (CCA). According to Borsley, agreement involves a superficial level of structure which is a syntactic level closely related to phonology.\(^29\)

Following these ideas, we claim that in our cases the postnominal adjective showing agreement with \(N_2\), hence singular agreement, establishes a syntactic relation which would in principle determine plural agreement, but, once linearisation provides an ordered string of elements, agreement with the second conjunct is possible. To be more explicit, our proposal to explain singular agreement in an example like \(\text{La lengua y cultura catalana}\) (the.F.SG language.F.SG and culture.F.SG Catalan.F.SG) is in line with Ackema & Neeleman (2004), who argue for the existence of rules that affect the featural content of terminals once linearization has taken place at PF. As shown in (50), when a structure like (46) (for \(\text{la lengua y cultura catalanas}\)) is linearized, \(N_2\), with a singular number feature, precedes and is adjacent to the postnominal \(A\), with a plural number feature. This linear relation enables a post-syntactic process of weakening/deletion of the values of the phi-features (\(c\)-features) of the adjective, followed by a process of feature-copying of the \(c\)-features of the immediately preceding noun \(N_2\). Only concord-features are involved in these post-syntactic processes since these are the only features interpreted by the PF interface. As a result, the adjective is spelled out with singular marking: catalana.

\begin{equation}
\text{(50) SYNTAX: } \text{La } [\text{\text{[CoP.NUMBER.PL ] [N1 lengua] y [N2 cultura\text{NUMBER.SG}]] A\text{NUMBER.PL}}]
\end{equation}

\(^29\) This is the level of order domains proposed in linearization-based HPSG.
PF (interface level between syntax and phonology)

**LINEARIZATION**: La lengua y cultura\textsubscript{NUMBER:SG} A\textsubscript{NUMBER:PL}

\[\text{--Weakening/deletion: } [A \, F_2] [B \, F_3] \rightarrow [A \, F_2] [B \, F]\]

La lengua y cultura\textsubscript{NUMBER:SG} A\textsubscript{NUMBER:PL}

\[\text{--Feature identification under linear adjacency: } [A \, F_2] [B \, F_2]\]

La lengua y cultura\textsubscript{NUMBER:SG} A\textsubscript{NUMBER:SG}

**SPELL OUT OF TERMINALS**: La lengua y cultura catalana

**PHONOLOGY**

In other words, agreement of the postnominal adjective with N\textsubscript{2} could then be treated as a case of context-sensitive spell-out and PF feature identification process of the kind proposed by Ackema & Neeleman (2004: chapters 6, 7). According to these authors, processes affecting the featural content of terminals are sensitive to local prosodic domains established at the level of initial prosodic phrasing after linearization. Benmamoun, Bhatia & Polinsky (2010) also find some initial indications that the choice of CCA in the structures they study is sensitive to prosodic constraints. Though it is possible that other relations among syntactic units, for example, relations relevant to the determination of phonological phrasing, are established at PF (Ackema & Neeleman 2004, Fox & Pesetsky 2005 and others), and even if it is possible that those initial prosodic relations may condition agreement as Ackema & Neeleman (2004) claim, they do not seem to interact with CCA in our structures. Indeed, Demonte & Pérez-Jiménez (in press) show the results of an experimental study that shows that agreement of postnominal adjectives with N\textsubscript{2} in the structures under study in this paper is independent of the grouping of N\textsubscript{2} and A in a local prosodic domain (phonological phrase). In other
words, agreement between the postnominal adjective and the second noun of the coordination is independent of the prosodic relation of these two terminals; it seems to be sensitive only to linear adjacency.

The proposal that linear adjacency plays a crucial role in CCA with postnominal adjectives in our structures receives empirical support from contrasts like the following:

(51) a. *la  radio y  television  pública  catalanas (cf. (10))
    the.F.SG radio.F.SG and television.F.SG public.F.SG Catalan.F.PL
    ‘The Catalan public radio and television’

b. *la  radio y  television  públicas  catalana
    the.F.SG radio.F.SG and television.F.SG public.F.PL Catalan.F.SG

In (51a), the adjective adjacent to N2 (pública) shows singular agreement, while the second adjective takes syntactic plural agreement (catalanas). However, the sequence A_{PL}–A_{SG} is ungrammatical (51b). In this case, the second adjective cannot show singular agreement with N2, since these two elements are not adjacent (the sequence A_{SG}–A_{SG} is also possible, since the second singular adjective is adjacent to the first one; the sequence A_{PL}–A_{PL} is also grammatical).

Moreover, in an example like (52), the singular adjective viejo (‘old’) can only be interpreted as modifying the second noun, not the whole coordinate phrase (a plural adjective, viejos, would be the only possibility). This is because in (52) there is no adjacency between the adjective and N2. Therefore, the singular number feature of the adjective cannot be a result of partial agreement between the adjective and N2.
Similarly, examples like (53) show that adjacency is required between the adjective and \( N_2 \) in partial agreement.

(52) \( La \ \text{maleta y bolso de rayas viejo.} \)

\( \text{the.F.SG suitcase.F.SG and bag.M.SG of stripes old.M.SG} \)

‘The suitcase and the old striped bag.’

(53) a. \( *La \ \text{radio y televisión recientemente pública han} \)

\( \text{the.F.SG radio.F.SG and television.F.SG recently public.F.SG have.PRS.3PL} \)

renovado su programación.

renewed their programming

b. \( La \ \text{radio y televisión recientemente públicas han} \)

\( \text{the.F.SG radio.F.SG and television.F.SG recently public.F.PL have.PRS.3PL} \)

renovado su programación.

renewed their programming

6. Conclusions

This paper illustrates the multifaceted nature of closest conjunct agreement. Its main points are the following. First, contrary to what has been claimed (Camacho 2003 and Heycock & Zamparelli 2005), in Romance languages a process of CCA inside DPs with coordinated Ns does exist. We have assessed the existence of CCA in Spanish exhaustively by examining a wide sample of corpus data, in which conjunctions of different individuals (singular count and group nouns) as well as of other entities (mass,
abstract and deverbal nouns) were considered. We have also demonstrated that the [D [NP y NP]] structures are not the result of ellipsis.

Second, singular (CCA) agreement between determiners, prenominal adjectives and the first noun of the coordination—in languages where DP coordinated subjects agree in plural with the VP—can be explained assuming that agreement relations are established derivationally due to the interaction of two different types of nominal features, namely, c-features and i-features, both being syntactically active inside the DP domain. Specifically, we have argued that number is a syntactic feature that emerges with a double face within the nominal feature geometry: as a mere formal (morphological/declensional) feature (concord) and as a referential feature (index). In our proposal, concord and index features are both syntactic/formal features that differ only with respect to the interface they give instructions to (concord features are interpreted at PF; index-features are interpreted at LF). Therefore, concord and index features are not designed to enter into two specific grammatical operations; there is no necessary link between concord-features and agreement inside the DP and index-features and agreement outside the DP—in the VP domain—. In our approach, there are not different agreement operations such as concord-agreement and index-agreement. Agree is a single syntactic operation that applies across all syntactic domains matching features irrespective of their type.

Third, we have explained the variation between singular and plural marking in adjectives following a coordination of NPs as a consequence of the assumption that in the mapping between syntax and phonology there is an interface post-syntactic component—PF—where syntactic terminals are linearised and where specific PF operations affecting the featural content of these terminals apply. Nonetheless, the deep
reasons why sometimes syntactic agreement does not surface with the expected features remains open to further research.
